

Dot-Code Guide -

Welcome to the guide! This will teach you on how to use my open source programming language called Dot Code. Dot Code is a simple programming language that is mainly made in Julia.

Notice: This is a guide on how to program in DotCode, the instructions for downloading and setup on DotCode will be in the README in the official Github repo: <https://github.com/fffoxie/dotcode>

Anyways now when we are done with that, let's learn how to program on DotCode!

Basic stuff - v1.0.0

Unlike Python and C#, DotCode uses only dots. Each dot represents a number (or a value) like. is 1 and .. is 2 and so on. Let me show you examples:

If you write: *That will be the same as saying: EC because there are 5 dots and 3 dots. This is the alphabet version. But you need to print it of course so what you do is:*

```
; ... = print C (; means print!)  
; .... = print DCAC
```

But there is a number version too!

```
; (... ..) = print 33214  
; (.....) = print 1012
```

But it might be exhausting to write Z or 10 so there is a simple version too:

```
;.(26) = print Z  
;.(26)) = print 26
```

Now it's way easier to write alphabets and numbers!

If statements:

If statements (and else,or,if) are different, instead of it being just, we use other symbols, here is a example:

```
& ... < ..  
;. (3) = if 3 is smaller then 2, print 3 (then this is not true, so it wont execute it)
```

more code, with else, or:

```
& ... < ..  
;. (3)
```

;.. = if 3 is bigger then 2, print 3 else print 2.

That is it for DotCode v.1.0.0
